A network graph visualization is shown on a white surface. It consists of several pushpins of various colors (blue, green, red, yellow) connected by thin brown string. The pushpins are arranged in a way that forms a complex network of interconnected nodes and edges. The background is a light gray color.

# Social Network Analysis: graph centralization

Song Yang, Ph.D.

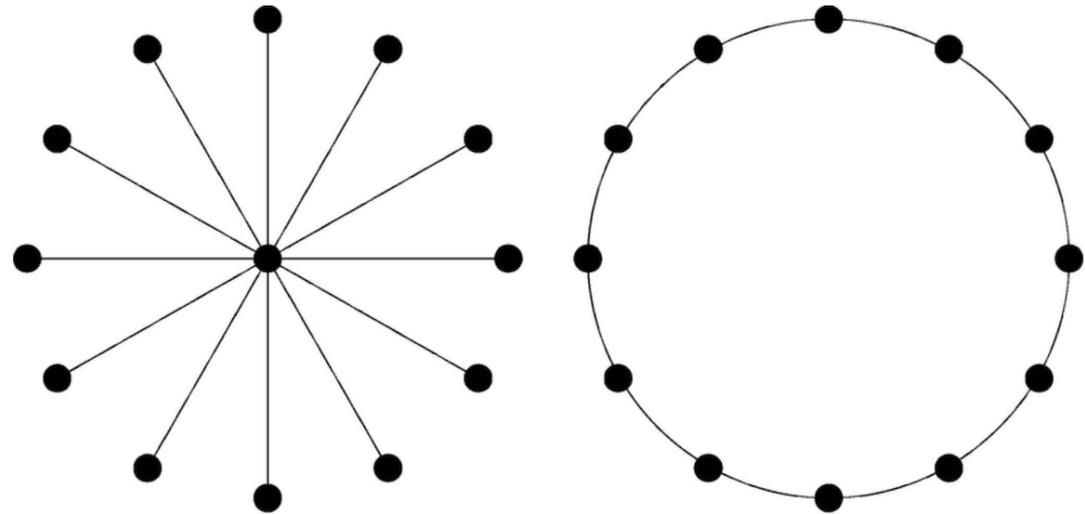

University of Arkansas

# Centralization $\neq$ Centrality

# Two extremes

- Star network → Highly centralized
- Circle network → Low centralization

# Why Centralization Matters?

Power concentration

Vulnerability of a network

Information flow control

Organizational hierarchy

Resilience to node removal

Example:

- Highly centralized network → Removing central node can collapse system.

# Degree Centralization

- Based on degree centrality
- Measures:
  - How unequal is the distribution of node degrees?
- Formula (conceptually):
  - $$C_D = \frac{\sum (max(d) - d_i)}{maximum\ possible\ sum}$$
- Where:
  - $d_i$  = degree of node i
  - max(d) = highest degree in network

# Computing degree centralization

---

- For an **undirected graph**, the normalized degree centralization is:

- $$C_D = \frac{\sum_{i=1}^n (d_{max} - d_i)}{(n-1)(n-2)}$$

- Where:

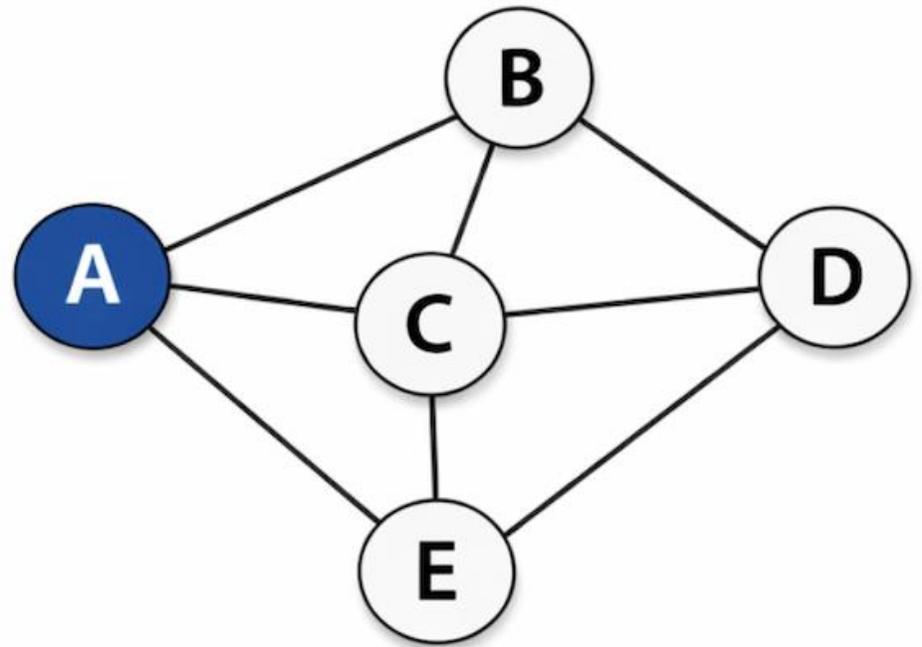

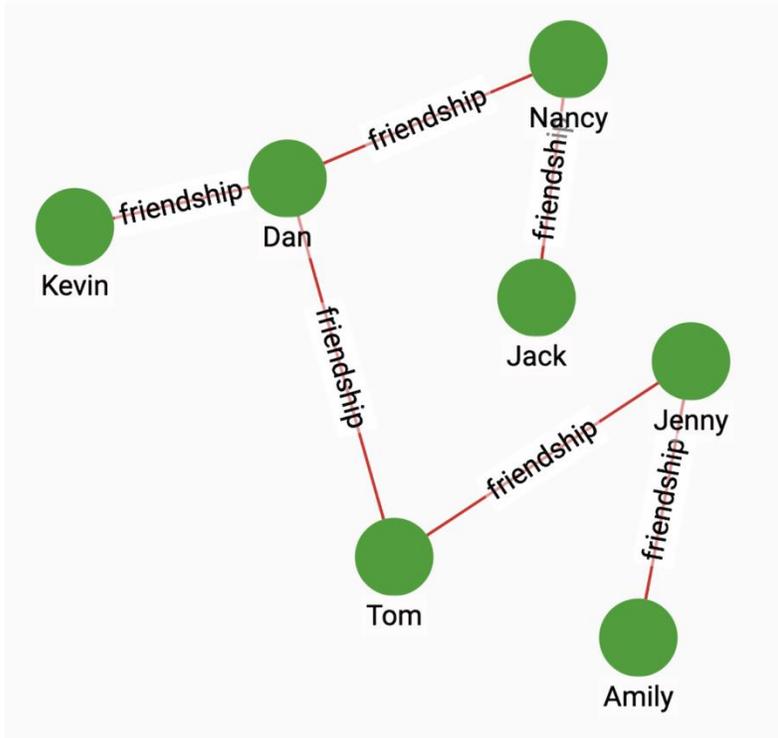

- $d_i$  = degree of node  $i$
- $d_{max}$  = maximum degree in the network
- $n$  = number of nodes
- $(n - 1)(n - 2)$  = maximum possible denominator (occurs in a star network)

# Interpreting degree centralization

- Range:
  - 0 → perfectly equal
  - 1 → star network (maximum centralization)

# exercise

---

# Applications

- Organizational hierarchy analysis

- Social media influencer detection

- Disease spread networks

- Criminal network analysis
